

1. Some cells take up glucose by a symporter powered by simultaneous entry of  $\text{Na}^+$ . The entry of  $\text{Na}^+$  provides free energy input of 10.8 kJ/mol under typical cellular conditions like external  $[\text{Na}^+] = 143 \text{ mM}$ ; internal  $[\text{Na}^+] = 14 \text{ mM}$ ; membrane potential = -50 mV; How large a concentration gradient of glucose at 310 K can be generated by this free energy.
2. The  $\text{Na}^+$  and  $\text{K}^+$  channel have similar structures and are arranged in similar orientation in the membrane. Explain how  $\text{Na}^+$  channel allows  $\text{Na}^+$  to flow inside the cell, while  $\text{K}^+$  channel allows  $\text{K}^+$  to flow outside the cell.
3. Digitalis inhibits the  $\text{Na}^+$ - $\text{K}^+$  ATPase pump. Explain how this inhibition leads to increased contraction of heart muscle.
4. Consider a neuronal cell with volume  $10,000 \mu\text{m}^3$  and a surface area of  $10,000 \mu\text{m}^2$ . If during opening of  $\text{Na}^+$  channel, 100,000  $\text{Na}^+$  ions flow inside the cell per ms per  $\mu\text{m}^2$  area, calculate by what percentage does the  $\text{Na}^+$  ion intracellular concentration change in 1 ms due to action potential.
5. Mutation in the  $\beta$ -subunit of acetylcholine receptor channel causes muscle weakness and rapid fatigue. Acetyl choline generated currents through acetylcholine receptor channels for both control and patient carrying mutation are shown below. What is the effect of mutation on channel function.

6. Calculate the equilibrium membrane potential
  - a. For  $\text{Na}^+$  (  $[\text{Na}^+]_{\text{in}} = 14 \text{ mM}$ ;  $[\text{Na}^+]_{\text{out}} = 143 \text{ mM}$ ; )
  - b. For  $\text{K}^+$  (  $[\text{K}^+]_{\text{in}} = 157 \text{ mM}$ ;  $[\text{K}^+]_{\text{out}} = 4 \text{ mM}$ ; )
